

CS 33
Midterm

All answers must be written on the answer sheet (last page of the exam).

All work should be written directly on the exam, use the backs of pages if needed.

This is an open book, open notes quiz – but you cannot share books or notes. An ASCII table is on the second to last page if you need it.

I will follow the guidelines of the university in reporting academic misconduct – please do not cheat.

NAME: _____

ID: _____

Problem 1: 28Problem 2: 30Problem 3: 42Total: 58

1. **C If You Can Solve This (28 points):** The following problem assumes the following declarations:

```
int x = rand();
int y = rand();
int z = rand();
unsigned ux = (unsigned) x;
unsigned uy = (unsigned) y;
```

For the following C expressions, circle either Y or N (but not both).

Handwritten notes for question a:
 $x \& 16$ is 01111111
 y is 00000000
 $(x \& 16) | y$ is 01111111
 $(x < 27) > 0$ is 1

a. $((x \& 16) | y) == y \Rightarrow (x < 27) > 0$

Always True?

Y ☒ N

b. $(x \wedge y) \wedge x + z == y + z$

☒ Y N

Handwritten notes for question c:
 $x \wedge x = 0$
 $0 \wedge y = y$

c. $x + y > 0 \Rightarrow (x > 0 \parallel y > 0)$

Y ☒ N

d. $(ux + uy) == (x + y)$

☒ Y N

Note that " \Rightarrow " represents an *implication*. $A \Rightarrow B$ means that you assume A is true, and your answer should indicate whether B should be implied by A – i.e. given that A is true, is B always true?

2. **Complete Dis-Array (30 points):** C code contains three different two dimensional arrays, listed in no particular order: white, black, and gray.

Array *white* is statically sized (i.e. size is known at compile time) and is a nested array. There is a function *setwhite()* which puts a value *val* into array *white* as indicated by row position *i* and column position *j*:

```
int white[SIZE][SIZE];  
void setwhite(int i, int j, int val);
```

Array *gray* is dynamically sized (i.e. size is not known at compile time) and is a nested array. There is a function *setgray()* which puts a value *val* into array *gray* as indicated by *i* and *j*:

```
int *gray;  
void setgray(int i, int j, int val);
```

Array *black* is statically sized (i.e. size is known at compile time) and is a multi-level array. There is a function *setblack()* which puts a value *val* into array *black* as indicated by *i* and *j*:

```
int *black[SIZE];  
void setblack(int i, int j, int val);
```

For example, *setwhite(i,j,val)* will set *white[i][j]* to the value *val*. *SIZE* is defined as:

```
#define SIZE 10
```

Based on the information above, you need to identify the disassembled code on the next page. Three functions are listed below, labeled set A , set B , and set C . These each represent either *setwhite*, *setgray*, or *setblack*. Fill in the blanks on the answer sheet to identify each function below.

set A ^{white}:

```

lea    (%rdi,%rdi,4),%rax
lea    (%rsi,%rax,2),%rax
mov     %rdx,0x600c60(,%rax,8)
retq

```

5 ^{no. of} $i=1$
 $rax=5$

5 $5 \times i$

$i=0$ 

$i=1$ 

$10 \times i$
 $rax = 2 \times 5 + j$

$8 \times (2 \times 5 + j) = 4 + 4 \times 5 + j$

$= 8 \times (10 + j) = 8 \times j + 8 \times 10$

$2 \times 4 \times 10$

set B ^{gray}:

```

movslq 0x200a14(%rip),%rax
imul    %rax,%rdi
add     %rdi,%rsi
mov     0x200a0e(%rip),%rax
mov     %rdx, (%rax,%rsi,8)
retq

```

set C ^{set black}:

```

mov     0x600c00(,%rdi,8),%rax
mov     %rdx, (%rax,%rsi,8)
retq

```

$8 \times rdi$ $i=0$ $i=1$ $i=2$ 

3. *This Problem is a Pain in My Big Endian (42 points):* Below we show the disassembled function `func0()` – compiled on an ia32 machine. The function reads one integer, using `scanf()`. Your job is to provide the input to `scanf()` that will result in this function returning the value 42.

Consider the following C code:

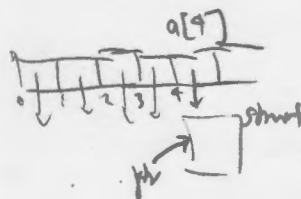

```
struct node_t {
    short key;
    union {
        long val;
        char label[8];
    } payload;
    struct node_t * next;
};
```

```
struct node_t * a[8];
```

```
int hash(int key)
{
    return (key & 7) ^ ((key >> 3) & 7);
}
```

```
void search(int key, int k)
{
    int i = hash(key);
    struct node_t * ptr;
    int j = 0;

    ptr = a[i];
    while (ptr)
    {
        if (ptr->key == key && j == k)
            printf("%s", ptr->payload.label);
        j++;
        ptr = ptr->next;
    }
}
```

224

2
16
16
16
224

256 16 1
0 2 9

key: 0000 1110 1001
8: 0000 1110 1001
0000 0011 1101
return val = 0000...0100 = 4

You need to figure out what is printed out when the following function call is performed:

`search(233, 4)`

The next three pages contain everything you need to solve this problem. Fill in all blanks on the answer sheet for partial credit.

Here is some gdb interaction which should prove useful – a breakpoint is set after the invocation of the function search:

```
(gdb) break *0x40097d
```

```
Breakpoint 1 at 0x40097d
```

```
(gdb) run
```

```
Starting program
```

```
Breakpoint 1, 0x00000000004009d7 in main ()
```

```
(gdb) print &a
```

```
$1 = (<data variable, no debug info> *) 0x600fa0.
```

```
(gdb) x/64bx 0x600fa0
```

Answer Sheet

Name: _____

1. Circle the correct responses:

Y ☒ N

☒ Y N

Y ☒ N

☒ Y N

2. Fill in the three blanks below with the name of a color (i.e. gray, white, or black) corresponding to the correct function call.

set A : set white

set B : set gray

set C : set black

3. Fill in all blanks below

The value of variable *i* in function search():

4

The value of *a[i]* in function search():

~~0x00000000~~ 0x601350

The value printed by the printf statement in function search():

we need the address 0x601150
